

Is a Prostate Biopsy Right for me?

IsoPSA provides information to help you and your doctor decide

IsoPSA is a simple blood test for men with elevated PSA (≥ 4 ng/mL) that can clarify whether cancer may be the cause.

IsoPSA provides valuable information that can help your doctor assess your prostate cancer risk and determine if a biopsy is right for you, whether it's your first biopsy or you've had one before.

How is IsoPSA different than the traditional PSA test?

The PSA test can only measure the total amount of PSA protein your prostate makes. IsoPSA can help tell if these proteins were produced by cancer cells.

Unlike other tests, medications commonly prescribed for enlarged prostate or benign prostate hyperplasia (BPH) don't affect IsoPSA test results.

How do I talk to my doctor about IsoPSA?

If you are interested in understanding your risk for high-grade prostate cancer and determining if a biopsy is right for you, consider asking your urologist about IsoPSA.

Here are some questions that can guide your conversation with your doctor to decide if you should try IsoPSA.

1. Based on my PSA levels and other risk factors, what is the likelihood that I may have prostate cancer?
2. Could my elevated PSA levels be due to something other than prostate cancer?
3. What are the risks associated with prostate biopsies?
4. Have you used IsoPSA? Am I a good candidate for IsoPSA?
5. How would you use my IsoPSA results to determine if I need a biopsy or not?
